

Contractibility and the Design of Research Agreements

By JOSH LERNER AND ULRIKE MALMENDIER*

We analyze how contractibility affects contract design. A major concern when designing research agreements is that researchers use their funding to subsidize other projects. We show that, when research activities are not contractible, an option contract is optimal. The financing firm obtains the option to terminate the agreement and, in case of termination, broad property rights. The threat of termination deters researchers from cross-subsidization, and the cost of exercising the termination option deters the financing firm from opportunistic termination. We test this prediction using 580 biotechnology research agreements. Contracts with termination options are more common when research is non-contractible. (JEL D86, L65, O31, O34)

The analysis of contract design is central to numerous areas in economics, ranging from labor economics and corporate finance to macroeconomics. An important determinant of contract design, introduced by the literature on incomplete contracts, is the observability and verifiability of actions and outputs (cf. Oliver D. Hart 1995). If key variables are not verifiable in front of judges, the contracting parties have to find alternative contractual mechanisms to induce the expected behavior, such as reallocating asset ownership.

We analyze how the design of contracts varies as underlying variables become harder or easier to verify. Specifically, we study both theoretically and empirically how the contractual rights of one party depend on the contractibility of innovative efforts to be performed by the other party.

Our empirical application is biotechnology research. Innovation in the biotechnology sector is frequently based on research agreements between a financing firm (typically a large pharmaceutical company) and a research firm (typically a smaller biotechnology company). Such agreements generally involve the financing firm providing support for a particular project in exchange for a share of ownership of any drugs that emerge from that project. A key difficulty for these collaborations is that the two parties have different goals. In particular, biotechnology researchers may use funds provided by the financing firm for other research projects or for refined analyses that are only academically relevant, an incentive problem that has been termed “project substitution” or “project cross-subsidization.”

We would like to thank Philippe Aghion, Susan Athey, George Baker, Pablo Casas-Arce, Pierre-André Chiappori, Jing-Yuan Chu, Bob Gibbons, Thomas Hellmann, Rebecca Henderson, Louis Kaplow, Robert Merges, David Robinson, Patrick Schmitz, David Sraer, Halla Yang, and Jeff Zwiebel, as well as workshop participants at the American Finance Association meetings, Columbia University, Harvard University, MIT, the NBER Organizational Economics Meeting, Simon Fraser University, and Stanford University, and two anonymous referees for helpful comments. We especially thank Oliver Hart and Jean Tirole for their detailed suggestions. We also benefited from conversations with a number of practitioners, especially Prem Das, Richard Douglas, Peter Finn, and Michael Lytton. Nageeb Ali, Maruti Didwania, Burak Guner, Camelia Kuhnén, Charmaine Lee, Felix Momsen, Philip Tzang, Anant Vasudevan, Kyle Woodward, Chenling Zhang, and especially Joanne Yoong provided excellent research assistance. We gratefully acknowledge financial support from the Coleman Fung Risk Management Research Center and Harvard Business School's Division of Research. We thank Mark Edwards for access to the ReCap data. All errors are our own.

We analyze the contractual response to this incentive conflict and how it depends on the contractibility of research. We first provide a simple model based on the property-rights theory of the firm, in particular Hart and John Moore (1988) and Georg Nöldeke and Klaus M. Schmidt (1995), which allows for multitasking in the sense of Bengt Holmström and Paul Milgrom (1991). If research effort is observable and verifiable, the incentive problem can be solved with a simple complete contract. Empirically, this is the case when the biotechnology researchers have to perform specific experiments on a specified lead product candidate. If, however, research is not contractible, option contracts are second-best optimal. The option contract gives the financing company the unconditional right to terminate the collaboration, in which case it also obtains broad property rights to the terminated project. The reversion of broad property rights from the research to the financing firm in case of termination provides incentives for the research firm not to divert effort to other projects. At the same time, the payments associated with termination prevent the financing firm from exercising the termination option opportunistically. The optimal option contract allows the financing firm to extract less profit, however, than a complete contract. Thus, the model predicts the use of such option contracts in contractually difficult environments, but not otherwise.

The model also implies that this prediction does not necessarily hold if the research firm is financially unconstrained. In that case, the parties can design an option contract that involves payments from the research firm to the financing firm upon termination. As a result, the contract with termination option is no more costly than any first-best contract: option contracts with liquid research firms allow financing firms to extract the first-best payoff whether research is or is not contractible. Hence, in this case there is no predicted relationship between contractibility and option contracts.

We test the predictions of our model in a novel dataset of 580 biotechnology research agreements. We first provide evidence of the underlying project cross-subsidization problem. The large number of simultaneous research alliances indicates that multitasking is commonplace for research firms in our sample. We then test whether research agreements are indeed more likely to employ termination clauses, coupled with the transfer of broader property rights to the financing firm, when research is noncontractible. Using the lack of a “specifiable lead product candidate” as a proxy for noncontractible research, we find the predicted relationship in the data. Moreover, the positive correlation of option contracts and noncontractibility is even stronger in the subset of financially constrained firms. It is insignificant for liquid research firms, though the differences in coefficients are not statistically significant.

We employ several additional tests to distinguish alternative explanations. One concern is that, in collaborations without a specifiable lead compound, the financing firm might be more likely to provide inputs into research beyond mere financing. The contract design might reflect this dual role rather than the lack of contractibility. Using a detailed analysis of the contractual language delineating the financing firm’s role and the patents awarded to the financing firm to measure its expertise in the field of the research agreement, we identify financing firms that might provide such nonfinancial input. After excluding these firms, the results are, if anything, stronger. Other alternative explanations, such as heterogeneity in uncertainty, in informational asymmetry, or in the “abilities” of the research firm, predict a correlation with specific rather than unconditional termination clauses and no reversion of property rights. The data reject these alternative correlations.

Overall, this paper makes three contributions. First, we shed light on a key incentive conflict in research collaborations, project cross-subsidization. We characterize this incentive conflict as moral hazard in a multitasking framework. Second, we provide new evidence on the empirical contract design of research agreements, in particular the use of unilateral and unconditional termination rights with broadened transfer of intellectual property. Third, we explain how the combination of termination and broadened property rights might remedy contracting difficulties.

Much of the prior literature analyzing “real-world contract design” has focused on complete rather than incomplete contracts (Pierre-André Chiappori and Bernard Salanié 2003). Notable exceptions are Steven Kaplan and Per Stromberg (2003, 2004), who provide exhaustive descriptions of venture-capital contract design, and George P. Baker and Thomas Hubbard (2003, 2004), who relate changes in contract design to a switch in the monitoring technology of truck drivers. Our approach resembles the latter: we relate an empirical proxy for contractibility to variations in contract design. Similar to previous work on strategic alliances (David Robinson and Toby Stuart 2007), we focus on specific contractual clauses, namely option rights to terminate. Our large, hand-collected dataset on research agreements allows us to address several concerns plaguing that literature, such as unobserved firm characteristics (via firm fixed-effects and firm-level controls), and to test directly competing explanations.

Prior empirical tests of the property-rights theory of the firm (e.g., Kirk Monteverde and David J. Teece 1982; Daron Acemoglu et al. 2004) have largely focused on “make or buy” decisions. The theoretical literature, however, pioneered by Sanford J. Grossman and Hart (1986) and Hart and Moore (1988, 1990), suggests that the contracting parties may design *any* suitable decision right to govern noncontractible actions. Our paper attempts to help fill this gap by focusing on the role of termination rights.¹ Compared to previous work on strategic alliance and venture capital contracts (Francesca Cornelli and Oved Yosha 2003; Wouter Dessein 2005; Schmidt 2003; Nöldeke and Schmidt 1998), we deemphasize the role of firm ownership. Our theoretical framework relates to the literature on financial contracting (Philippe Aghion and Patrick Bolton 1992; Aghion and Jean Tirole 1994). Other papers address the selection of alliance projects, e.g., a “lemons” problem, whereby biotechnology companies license only their less promising drugs (Gary Pisano 1997). Patricia M. Danzon, Sean Nicholson, and Nuno S. Pereira (2005) find no empirical support for this hypothesis. Ilan Guedj (2006) analyzes opportunistic *ex post* behavior after an agreement is signed. We ask how contract design can anticipate such behavior. The incentive conflict of “academic” versus “commercial” research has been analyzed by Iain Cockburn, Rebecca Henderson, and Scott Stern (1999).

The remainder of the paper is organized as follows. In Section I, we present stylized facts on biotechnology research collaborations. Section II presents a model that reconciles the empirical contract design with the observed incentive conflicts. Section III introduces the data. We test the predictions and alternative hypotheses in Section IV. Section V concludes the paper.

I. Incentive Conflicts in Biotechnology Research Collaborations

Innovative activities in the biotechnology sector increasingly take place as research collaborations. While the initial biotechnology firms relied primarily on capital raised on public markets, research alliances surpassed public offerings in the 1990s as the dominant source of financing.² These research collaborations consist of three phases: research, development, and marketing and sales. Typically, a pharmaceutical company provides the financing and a biotechnology company performs the bulk of the research. The development of the drug is undertaken jointly. Marketing and sales are handled mostly by the financing company. As the dominant research-performing entity, the biotechnology firm receives the intellectual property rights but commits to license the relevant patents and know-how to its partner. The right to manufacture the product may be assigned to one of the parties or divided between the two. Most profits from the final project go

¹ Similar to Baker, Robert Gibbons, and Kevin Murphy (2002) and Hart and Holmström (2008), we emphasize a contracting problem that differs from the classic problem of relationship-specific investment.

² See Lerner and Robert P. Merges (1998).

to the financing company, though the research company reaps a percentage via the royalties from licensing.

The pervasiveness of research agreements in the biotechnology sector is puzzling, since the interests of the two partners are often misaligned. From a number of interviews with executives specializing in management, technology transfer, and legal affairs, we learned that project substitution and project cross-subsidization by biotechnology researchers are, in fact, major concerns of financing firms entering into research agreements. While it is the objective of the financing firm to develop a certain viable and profitable drug, the research firm has multiple interests. On the one hand, the researchers are also interested in developing the proposed drug and ensuring future cash flows. On the other hand, they are typically juggling several research projects. Some projects may be in collaboration with other pharmaceutical or biotechnology firms. Others may be the development of wholly owned products, from which the research firm receives all the profits and whose success is particularly valued by equity markets as an indicator of the acumen of the research firm's management. As a result, researchers are tempted to employ resources from a specific research agreement on other projects. This was, for instance, the claim in the law suit Alkermes filed in 1993 against its contracting partner Cortex Pharmaceuticals. Alkermes alleged that Cortex's research on a calpain-inhibiting drug for cerebral vasospasm violated Alkermes's exclusive right to develop applications for neurological disorders.³

In addition to these commercial conflicts, researchers in biotechnology companies are often more academically oriented than the financing firms. Many biotechnology firms are founded by long-time academics who still want to have an impact on the scholarly discussion. They often employ postdoctoral students who are considering an academic career. Furthermore, their reputation in the market for future research agreements depends to a large extent on the external assessment of their research abilities. These pressures may lead to biotechnology firms pursuing research that is more fundamental than the financing firm would like and seeking publication before the financing company wishes the findings to become known.

The 1978 research agreement between ALZA, a California-based drug delivery company, and the Swiss pharmaceutical giant Ciba-Geigy illustrates the concerns about opportunistic behavior of the research firm. As described in more detail in Web Appendix A, numerous tensions arose over the type of collaborations that ALZA researchers sought to conduct with third parties and over publications by ALZA scientists. The parties were not able to remedy the divergence of interests contractually, leading to the dissolution of the research collaboration at the end of 1981.⁴

In a subset of cases, the parties can remedy this incentive conflict directly by specifying the exact research activities to be undertaken by the researchers. If the parties have identified a specific lead product candidate at the beginning of the collaboration, it is relatively easy to separate out unrelated research. In many cases, however, the exact lead product candidate is not yet specifiable and the research agreement is entered without a clear product in mind. The research agreements, then, have to account for contractual incompleteness—for having “too many” future contingencies that are “too hard to think of” to contract upon them. In these cases, it is difficult to delineate the boundaries of a project. In this paper, we exploit this variation in contractibility, both from a theoretical and an empirical perspective.

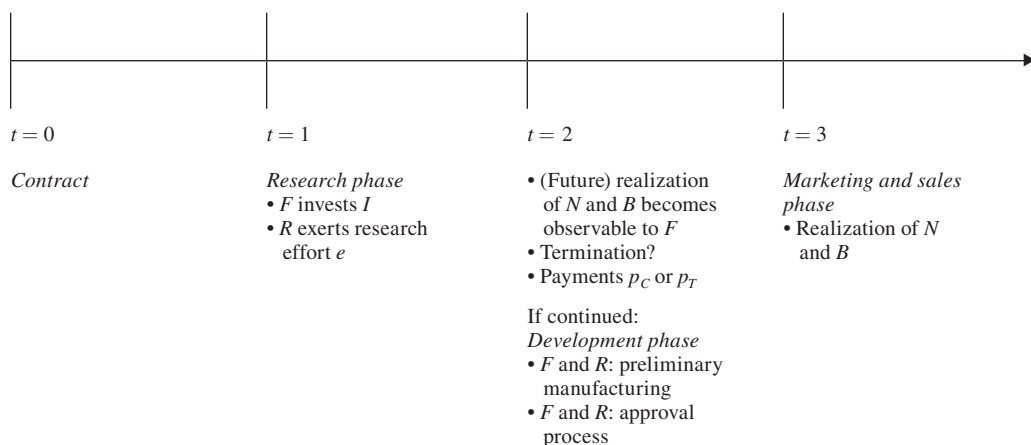

FIGURE 1. TIMELINE

II. Model

We present a simple model that illustrates how variations in contractibility affect the design of research agreements. The model also illustrates the role of financial constraints.

A. Baseline Setup

We consider a research firm R and a financing firm F , both risk neutral. (All variable definitions are listed in Appendix A.) The model has four periods, depicted in Figure 1: contracting at $t = 0$, financing and research at $t = 1$, development at $t = 2$, and marketing and sales at $t = 3$. We assume initially that R is credit constrained. Hence, there is no possibility of monetary transfers from R to F . If, at $t = 1$, F provides financing I , then R can perform research. R 's research effort e at $t = 1$, yields an intermediate product (a technology) at $t = 2$. If advanced through development, marketing, and sales, this technology generates two types of nonnegative and noncontractible surplus: "narrow" (or "commercial") surplus N from the sales of the envisioned product, and "broad" (or "scientific") surplus B , which represents scientific reputation and profits from unrelated discoveries. For simplicity, we assume that both types of surplus are deterministic.⁵

The basic conflict arises from R 's interest in broad (scientific) surplus B , which does not benefit F . Specifically, we assume that, in the research phase (at $t = 1$), R can either focus on the narrow project specified in the research agreement or engage in broader research. Narrow research effort e_N generates high narrow surplus, \bar{N} , but low broad surplus, \underline{B} , while broad research effort e_B results in low \underline{N} and high \bar{B} . We assume $\bar{N} > I$. Both types of surplus are realized after commercialization at $t = 3$.

The amount of surplus extracted in $t = 3$ depends on (i) whether the parties continue to collaborate at $t = 2$, and (ii) the allocation of property rights. As for (i), the full amount of narrow surplus N is generated only if the parties continue to collaborate. If they terminate the collaboration after $t = 1$, they generate strictly less, a portion αN , $\alpha \in (0, 1)$. The ex post efficiency loss from termination, $(1 - \alpha)N$, reflects the specialization of biotechnology researchers and the search costs

⁵ The results are unchanged if the surplus is stochastic and its expected value depends only on R 's effort.

to find a new partner. Broad surplus B , instead, does not depend on continued collaboration, as it captures the value of future projects with different partners and general scientific reputation.

As for (ii), the surplus accrues to the holder of the intellectual property rights. Rights to narrow and to broad surplus can be contracted on separately. Narrow rights allow the holder to sell the envisioned product of the collaboration, i.e., to reap N . Broad rights allow the holder to claim the intellectual ownership and to develop and sell side products, i.e., to reap B . We assume that these rights are of different value for F and for R . If F obtains the narrow rights, it can extract the full amount, i.e., N in case of continuation and αN in case of termination. If R obtains the narrow rights, it cannot extract any portion of N . This assumption captures the fact that success in the final stages depends on the capacity of F to undertake large-scale manufacturing, as well as on F 's marketing and distribution channels. On the other hand, R can extract the full broad surplus B if it has the broad rights, while F extracts only a portion εB , $\varepsilon \in (0, 1)$ if granted the broad rights. This assumption captures the idea that future research that builds on the broad technology and enhances scientific reputation is more valuable to the academically oriented researchers than to the financing firm. For simplicity, we focus on the case⁶

$$(A1) \quad \underline{B} > \varepsilon \bar{B}.$$

We also assume that

$$(A2) \quad R \text{ chooses } e_B \text{ if indifferent between } e_N \text{ and } e_B.$$

Assumption (A1) can be interpreted as a reduced-form substitute for modeling nontransferable benefits for R from the broader research, such as acquiring nontransferable general human capital.

We assume that F makes a take-it-or-leave-it offer to R and that there is no renegotiation.⁷ The assumption of a take-it-or-leave-it offer reflects the fact that there are many research firms seeking funding relative to the number of potential capital providers.

We do not model the costs of R 's research effort explicitly. Rather, we set the cost of effort e_N or e_B equal to zero and assume that R is willing to sign a contract if and only if its payoff is at least the value of the broad rights after narrow effort, \underline{B} :

$$(A3) \quad \text{The reservation utility of } R \text{ is } \underline{B}.$$

We consider three contractual scenarios. First, we derive the optimal contract under the assumption that e is contractible. Second, we derive the optimal no-option contract under the assumption that R 's research is observable⁸ at $t = 2$ but not verifiable. Third, we introduce option rights and ask whether they allow the financing firm to extract a higher payoff. In particular, we consider the option to terminate the research collaboration after $t = 1$, i.e., after F has observed

⁶ This assumption reduces the number of subcases (see Appendix B). It guarantees that, when F gets the broad rights, the value of B to F is always less than the minimal amount R requires to sign a contract with F , i.e., R 's outside option to sign a contract.

⁷ There is scope for renegotiation after R has exerted the research effort e . We derive the solution with renegotiation in Web Appendix B. (See also the extended version in NBER Working Paper 11292, Appendix C.)

⁸ We also develop an alternative model where F cannot observe e directly but infers it from the stochastic intermediate research output at the end of period 1. The alternative model also removes the assumption that the final surplus N is noncontractible (which is a simplified way to capture the role of F in the last phase of the collaboration and the potential moral hazard problems) and allows for royalty fees. Introducing signal extraction and surplus sharing complicates the model, but the basic trade-off and determinants of the use of option rights are the same.

e and thus knows the (future) surplus resulting from e . The contractual use of termination rights implies that the courts can observe termination, i.e., which party (if any) decided not to continue the collaboration. We assume

(A4) F terminates if indifferent between termination and continuation.

The focus on termination rights reflects the empirical purpose of the model.⁹ We derive the optimal contract among all option contracts that condition intellectual property rights on the decision to terminate. In our framework, a contract specifies:

- (i) the initial payment I of the financing firm at $t = 1$,
- (ii) the termination rights (if any) at $t = 2$,
- (iii) the payments p from F to R at $t = 2$, and
- (iv) the narrow and broad property rights of F and R .

In the benchmark scenario of contractible effort e , the parties can condition (ii)–(iv) on e . If e is observable but not verifiable, (ii)–(iv) cannot be conditioned on e . If option contracts are used, (ii)–(iv) can be conditioned on continuation or termination. We denote payment in case of continuation C as $p_C \geq 0$ and in case of termination T as $p_T \geq 0$, and the property rights o assigned to F as o_C in case of continuation and o_T in case of termination. Hence, for a given action $a \in \{C, T\}$, $o_a = \emptyset$ denotes that F receives no intellectual property rights after action a , $o_a = B$ that F receives broad rights, $o_a = N$ that F receives narrow rights, and $o_a = B + N$ that F receives both broad and narrow rights. Figure 2 summarizes the payoffs for both parties under each scenario.

Contractibility.—If e is contractible, F obtains the maximum attainable payoff $\bar{N} - I$ by contracting on e_N , reserving the rights to N for itself, allocating B to R , and setting $p = 0$.

To see that $\bar{N} - I$ is the maximum attainable payoff, note that the minimum payment from F to R satisfying R 's participation constraint is $p = \underline{B}$ if R does not obtain the rights to B and $p = 0$ if R obtains at least the broad rights. Employing the minimum price and maximizing F 's payoff over e and across the different contract scenarios, we find that F 's payoff is maximized under $e = e_N$ and $o = N$, resulting in a net payoff of $\bar{N} - I$ for F and of \underline{B} for R .

Note that this is not the surplus-maximizing outcome if $\bar{B} + \underline{N}$ is larger than $\underline{B} + \bar{N}$. In this case, the financial constraints of the research firm (combined with our restriction to nonstochastic contracts) prevent the parties from achieving the first-best outcome and having the research firm compensate its partner ex ante, akin to Aghion and Tirole (1994).

Limited Contractibility without Options.—If e is observable but not verifiable, the parties cannot condition payments and actions on e . Thus, in contracts without option rights, R will always choose e_B (given (A4) and $\bar{B} > \underline{B}$). As in the case of contractible e , it is profit maximizing for F to acquire only the narrow rights since this dispenses with the need to pay R 's reservation wage.

⁹ Most alternative option contracts are hard to implement practically. Consider, for example, a contract that gives F the option to seize intellectual property rights directly, without termination. In practice, F cannot simply “seize” rights from R , and it is hard to imagine a contract that obliges R to grant both narrow and broad rights at the will of F while continuing to collaborate.

| | F 's rights | F 's payoff | R 's payoff |
|--------------|-------------------|--------------------------------------|---------------|
| Continuation | $o_C = \emptyset$ | $-p_C - I$ | $B + p_C$ |
| | $o_C = N$ | $N - p_C - I$ | $B + p_C$ |
| | $o_C = B$ | $\varepsilon B - p_C - I$ | p_C |
| | $o_C = N + B$ | $N + \varepsilon B - p_C - I$ | p_C |
| Termination | $o_T = \emptyset$ | $-p_T - I$ | $B + p_T$ |
| | $o_T = N$ | $\alpha N - p_T - I$ | $B + p_T$ |
| | $o_T = B$ | $\varepsilon B - p_T - I$ | p_T |
| | $o_T = N + B$ | $\alpha N + \varepsilon B - p_T - I$ | p_T |

FIGURE 2. PAYOFFS

Thus, F 's payoff is $\underline{N} - I$, and R gets \bar{B} if a contract is signed. However, if $\underline{N} < I$, F does not make any offer and the parties forgo the narrow and broad surplus. We denote the set of contracts that maximize F 's profit in the class of contracts without options (including “no contract”) as A_{NO}^* and the resulting payoff for F as Π_{NO}^* , with $\Pi_{NO}^* = \max\{\underline{N} - I, 0\}$. If a contract is signed, R extracts a rent of $\bar{B} - \underline{B}$ beyond the reservation utility.

Limited Contractibility with Options.—We now ask whether a broader class of contracts allows F to reap a higher payoff. In particular, we consider the role of termination rights. We denote as $A_O = (i, p_C, p_T, o_C, o_T)$ contracts that assign the option right to terminate to party i , $i \in \{R, F\}$. We first show that the empirically observed option contract—i.e., an option contract that grants F the right to terminate after R 's initial research effort ($i = F$), and allocates both the narrow and the broad rights to F if F terminates ($o_T = N + B$), but only narrow rights if F continues ($o_C = N$)—may yield a higher payoff for F than the second-best no-option contract A_{NO}^* . We start by showing which option contracts of this type induce the researchers to focus on the narrow surplus.

LEMMA 1: *The empirically observed option contract ($i = F$, $o_C = N$, $o_T = N + B$) implements e_N if and only if*

$$(1) \quad (1 - \alpha)\bar{N} - \varepsilon \underline{B} > p_C - p_T \geq (1 - \alpha)\underline{N} - \varepsilon \bar{B}.$$

PROOF.

See Appendix B.

To gain some intuition for double-inequality (1), note that the upper bound of the price differential $p_C - p_T$ between continuation and termination, $(1 - \alpha)\bar{N} - \varepsilon \underline{B}$, ensures that F chooses continuation after e_N . The gain from continuation conditional on R performing e_N is the share of narrow surplus that would be lost under termination, $(1 - \alpha)\bar{N}$, minus the share of broad surplus that F would gain under termination (after the reversion of broad property rights), $\varepsilon \underline{B}$. This gain has to be larger than the extra amount to be paid in case of continuation rather than termination. Similarly, the lower bound $(1 - \alpha)\underline{N} - \varepsilon \bar{B}$ ensures that F chooses termination after e_B : the gain from continuation conditional on R performing e_B does not justify the price differential to be paid in case of continuation. Note that the higher F 's outside options are, i.e., the shares α and ε of surplus F retrieves after terminating the collaboration with R , the cheaper it is for F to induce the desired effort e_N : the minimum extra amount to be paid in case of continuation becomes smaller.

We can now characterize, within the class of incentive-compatible option contracts satisfying (1) above, the payoff-maximizing contracts. Denote the left-hand side of (1), $(1 - \alpha)\bar{N} - \varepsilon\bar{B}$, as Γ and the right-hand side of (1), $(1 - \alpha)\underline{N} - \varepsilon\bar{B}$, as Δ .

LEMMA 2: *In the set of option contracts $(F, p_C, p_T, N, N + B)$ that implement e_N , any contract with*

$$(2) \quad p_C \begin{cases} = \Delta \\ = 0 \\ = 0 \end{cases} \quad \text{and} \quad p_T \begin{cases} = 0 \\ \in [0, -\Delta] \\ \in (-\Gamma, -\Delta] \end{cases} \quad \begin{matrix} \text{if } \Gamma > \Delta \geq 0 \\ \text{if } \Gamma > 0 > \Delta \\ \text{if } 0 \geq \Gamma > \Delta \end{matrix}$$

maximizes F 's payoff.

PROOF:

See Appendix B.

Intuitively, Γ and Δ capture the differences in F 's payoff in case of continuation (relative to termination) if R chooses e_N or e_B , respectively. To ensure that F does not choose continuation after the undesired broad effort e_B , an optimal contract requires F to pay the gain from continuation after e_B , Δ , to R upon continuation (if there is a gain, i.e., if $\Delta > 0$). If R were not financially constrained, F could implement termination at zero cost, i.e., with $p_C = 0$, by setting $p_T < 0$. But since such a contract is not possible, termination after e_B is not attractive unless F sets a positive continuation price. Similarly, to ensure that F does not choose termination after the desired effort e_N , an optimal contract requires F to pay more than the gain from termination, $-\Gamma$, to R upon termination (if there is a gain, i.e., if $\Gamma < 0$).

We now denote with \hat{A}_O all option contracts $(F, p_C, p_T, N, N + B)$ satisfying (2). F 's payoff from a contract \hat{A}_O is $\hat{\Pi}_O = \bar{N} - \max\{0, \Delta\} - I$, and R 's payoff is $\bar{B} + \max\{0, \Delta\}$. Lemma 3 states the conditions under which $\hat{\Pi}_O > \Pi_{NO}^*$, i.e., under which F prefers any contract \hat{A}_O to any second-best no-option contracts, A_{NO}^* :

LEMMA 3: *The payoff of F under option contracts \hat{A}_O , is strictly higher than the payoff under no-option contracts A_{NO}^* if and only if $\bar{N} - \max\{\underline{N}, I\} > \Delta$.*

PROOF:

See Appendix B.

Lemma 3 shows that the profitability of an option contract relative to a no-option contract depends on two effects. First, it depends on how much e_N increases the narrow surplus relative to e_B , $\bar{N} - \underline{N}$. Only if the difference is large is it worthwhile for F to induce e_N at the cost of p_C (rather than paying p_T). Second, the profitability of the option contract depends on F 's outside options in case of termination. The more surplus F can reap without the continued collaboration of R —either narrow surplus (high α) or broad surplus (high ε)—the greater is the threat for R that F will terminate and the cheaper is the option contract for F .

Lemmas 1–3 jointly imply the positive incentive and payoff effects of a specific type of option contract: An option contract that assigns F the right to terminate after $t = 1$ and, only in case of termination, also assigns F broad property rights induces R to exert e_N and may allow F to reap a higher payoff than the maximum payoff from contracts without option rights.

We now consider the entire class of option contracts (i, p_C, p_T, o_C, o_T) and show that option contracts \hat{A}_O are the payoff-maximizing choice. We denote with A_O all option contracts other than \hat{A}_O and with Π_O their payoff. We show:

PROPOSITION 1: *All other option contracts A_O lead to a strictly smaller payoff than \hat{A}_O whenever \hat{A}_O is preferred to the unconditional contract, i.e.,*

$$\Pi_O \leq \Pi_{NO}^* \quad \vee \quad \Pi_O < \hat{\Pi}_O.$$

PROOF:

See Appendix B.

Proposition 1 implies that, as long as F sticks to the unconditional contract whenever indifferent—e.g., due to other, unmodeled frictions in option contracting—we should observe either the unconditional contract or \hat{A}_O , but no other option contracts. This result implies the following empirical prediction:

PREDICTION 1: *Option contracts assigning the right to terminate with reversion of broad property rights to the financing firm are more likely if research activities are not contractible.*

The model illustrates that the incentive conflict between the financing firm and the research firm may prevent the parties from entering a research collaboration whenever research activities are not contractible. The parties can overcome this problem by using an option contract. However, to prevent opportunistic exercise of the option right to terminate, payments conditional on termination need to be specified. Given the financial constraints of the research firm and the required difference between continuation and termination payments, the financing firm may not extract the full profit $\bar{N} - I$. In other words, the preferred option contract is costly relative to the first-best outcome when e is contractible.

B. Set-Up with Financially Unconstrained Research Firms

We now introduce financially unconstrained firms into the model and show that the relationship between option contracts and contractibility does not necessarily hold. We assume that, as before, R requires funding I at $t = 1$, but is liquid at $t = 2$, so that prices p_C and p_T can be negative.¹⁰

To show that Prediction 1 does not hold with liquid firms, we consider the case where it is socially optimal to implement e_N , i.e., $\bar{N} + \underline{B} > \underline{N} + \bar{B}$. Since Lemma 1 does not depend on the nonnegativity constraint on p , e_N can be implemented, as before, using an option contract with $i = F$, $o_C = N$, and $o_T = N + B$, and prices p_C and p_T such that $(1 - \alpha)\bar{N} - \varepsilon\underline{B} > (p_C - p_T) \geq (1 - \alpha)\underline{N} - \varepsilon\bar{B}$. However, F can now set $p_T < 0$ if necessary to satisfy double-inequality (1). As a result, the set of option contracts that maximize F 's payoff (Lemma 2) changes:

LEMMA 2': *In the set of option contracts $(F, p_C, p_T, N, N + B)$ that implement e_N , setting $p_C = 0$ and $-\Gamma < p_T \leq -\Delta$ maximizes F 's payoff.*

¹⁰ R may become liquid due to the technology developed in $t = 1$ or inflows from other projects. Assuming that R is illiquid ex ante, but liquid ex interim (rather than liquid throughout) allows us to mirror the previous analysis: research requires F to contribute initial funding.

PROOF:

With $p_C = 0$ and $-\Gamma < p_T \leq -\Delta$, e_N is implemented by Lemma 1. Since R 's equilibrium payoff under this contract is its reservation utility \underline{B} , F 's profit cannot be increased further.

An immediate implication of Lemma 2' is that the option contract also maximizes F 's payoff if research effort is contractible: it achieves the maximum joint payoff for R and F while paying R just its reservation utility. Hence, in contrast to the setting with constrained firms, the use of option contracts is not necessarily correlated with contractibility for unconstrained firms.

Moreover, the set of payoff-maximizing option contracts changes. If R is liquid, option contracts that do not involve reversion of broad property rights upon termination also induce the maximum payoff for F , e.g., $(F, p_C, p_T, N, \emptyset)$. (See Lemmas 1'' and 2'' in Appendix B.)

We conclude that the use of option contracts covaries with the contractibility of research efforts for financially constrained research firms but not necessarily for liquid firms. If a research firm is financially unconstrained, various types of option contracts *and* no-option contracts allow the financing firm to extract the full surplus. Thus, the option contract may or may not be employed, regardless of the contractibility of research efforts:

PREDICTION 2: *While research agreements with financially constrained research firms employ the option contract only if research is noncontractible, research agreements with liquid research firms may employ the option contract whether or not research is contractible.*

III. Data

To test the predictions of the model we collected a novel dataset of research agreements. We sought to employ as large a sample of biotechnology research agreements as possible, in which the financing firms are either pharmaceutical or large biotechnology firms.

Our main source is a database compiled by Recombinant Capital (ReCap), a San Francisco-based consulting firm that has tracked the biotechnology industry since 1988. The data is typically licensed by major pharmaceutical, accounting, and law firms for a considerable annual fee.

Most contracts in ReCap's data are with publicly traded research firms. Public firms are required by the SEC to disclose "material transactions." Agreements representing 5 percent or more of a firm's revenues are typically considered material. Since most research firms have modest revenues, this criterion is often triggered. (The larger financing firms rarely file research agreements.) Biotechnology firms tend to interpret the requirement conservatively and not only report that they enter into strategic alliances, joint ventures, and licensing agreements, but also file the contracts as amendments to 10-K, 10-Q, S-1, or 8-K statements.

Not all filings are by public firms. Research firms that subsequently go public (or file to go public and then withdraw the offerings) typically disclose research agreements signed earlier that are still active. In addition, a number of states require privately held companies with employee stock option plans to file material documents.

ReCap seeks to create a comprehensive dataset of the agreements in the biotechnology industry, based on SEC and state filings, news accounts, and press releases. ReCap summarizes the basic information on all identified agreements, including the parties, the date of the agreement, the stage of the lead product at the time of signing, and the technologies and diseases that are the focus of the agreement. For a subset of the agreements that have been filed in a public document, ReCap obtains more detailed information. The initial coding is often done at the request of clients. For example, a client may request that a number of transactions in a given technology or by a certain firm be analyzed. In other cases, ReCap analyzes agreements at its own expense. These

TABLE 1—SAMPLE CONSTRUCTION

| Sample construction, starting from ReCap universe | Observations |
|---|--------------|
| <i>Agreements analyzed by ReCap, entered into through end of 2001, as of January 2003</i> | 1,108 |
| Less agreements involving universities, nonprofits, and hospitals (311) | 797 |
| Less “marketing only” agreements (127) | 670 |
| Less agreements involving renegotiations of existing agreements (62) | 608 |
| Less agreements involving three or more parties (14) | 594 |
| Less non-arm’s-length agreements (10) | 584 |
| Less duplicated agreements (3) | 581 |
| Less agreements no longer present in ReCap as of July 2006 (1) | 580 |
| <i>Additional data-gathering steps</i> | |
| ReCap disease/keyword data available | 580 |
| Financing category determined from contract analysis | 580 |
| Patent data available* | 580 |
| Carter-Manaster rank data available | 526 |
| Financial Health Index data available | 551 |
| Data on previous alliances between two firms available | 551 |
| All above data available | 483 |

*Five agreements with insufficient keywords are coded as 0.

tend to be particular “significant” agreements, either in terms of the science or the magnitude of the contractual payments.

An important question is what type of selection bias ReCap’s procedure creates. Contracts with well-established and scrutinized research firms, in particular firms that are successful enough to go public later, are overrepresented in our sample. As in virtually all studies examining the financing of and contracting by private firms, this implies some “backward looking bias.” One way in which this selection might affect our analysis is that the types of information problems we highlight in this paper are *less* likely to be present. Factors triggering the ex post success of our sample firms might be partially observable ex ante and lead to less concern about project substitution. In that case, our sample is likely to underrepresent the importance of contractual remedies to project substitution. Alternatively, ex post successful firms might have had a better reputation and a greater ability to enter into a large number of alliances at the time of the research agreements. In that case, contractual remedies of the incentive misalignment may be more important than in a comprehensive sample of all research agreements. In both cases, however, the bias affects only the strength of the estimated effect and not, directionally, whether the use of option contracts helps remedy project substitution.

Based on the full ReCap database, we construct our sample using the procedure summarized in Table 1. We start from the set of all analyzed agreements through the end of 2001. We eliminate transactions that did not involve a biotechnology company as the research firm (i.e., contracts with universities, nonprofit organizations, government bodies, and hospitals, as well as a few cases of agreements between two pharmaceutical firms),¹¹ those without research and product development components (i.e., contracts that do not fall into at least one of the ReCap classes “Collaboration,” “Co-Development,” “Development,” and “Research”), renegotiations or extensions of existing agreements (i.e., using the ReCap classification scheme and the actual text

¹¹ We focused on (nonsubsidiary) biotechnology firms as identified by ReCap and the industry classifications in two major databases of high-technology firms, Venture Economics (classes 4100 to 4390 and 4600 to 4900) and VentureOne (classes 2300 to 2499), which track firms backed by angel investors, corporate sponsors, and venture capitalists. As a diagnostic check, we examined whether the list of biotechnology firms would change when we used another source. We compiled the names of stand-alone firms dedicated to biotechnology listed in the various editions (through 2001) of the *BioScan Directory*, but found few differences.

TABLE 2—SUMMARY STATISTICS

| Variable name | Observations | Mean | S.D. | Min. | Max. | Median |
|---|--------------|----------|--------|----------|----------|----------|
| Date | 580 | 1,995.85 | 3.73 | 1,980.04 | 2,001.71 | 1,996.88 |
| No specifiable lead product | 580 | 0.37 | 0.48 | 0 | 1 | 0 |
| Unknown if specifiable lead product | 580 | 0.11 | 0.31 | 0 | 1 | 0 |
| Agreement involves diagnostic product | 580 | 0.13 | 0.34 | 0 | 1 | 0 |
| Agreement involves veterinary product | 580 | 0.05 | 0.23 | 0 | 1 | 0 |
| Agreement between two biotechnology firms | 580 | 0.17 | 0.37 | 0 | 1 | 0 |
| Research firm's revenue in prior fiscal year | 558 | 11.47 | 37.21 | 0 | 523.22 | 0.71 |
| Research firm's cash flow in prior fiscal year | 535 | 2.57 | 176.14 | −331 | 2,398.26 | −6.66 |
| Research firm's net income prior fiscal year | 558 | 1.38 | 189.12 | −351.95 | 2,474.34 | −7.48 |
| Research firm's cash holdings in prior fiscal year | 551 | 46.04 | 134.69 | 0 | 1,452.36 | 12.53 |
| Financial Health Index | 551 | 0.62 | 0.27 | 0 | 1 | 0.67 |
| Patent awards to the research firm at the time of the research agreement signing | 580 | 8.66 | 20.12 | 0 | 178 | 1 |
| Number of previous research agreements between financing and research firms | 551 | 0.11 | 0.40 | 0 | 3 | 0 |
| Total number of research agreements signed by research firm in previous 3 years | 580 | 6.39 | 6.78 | 0 | 45 | 4 |
| Total number of research agreements signed by research firm in previous 3 years with any technology match | 580 | 4.77 | 6.56 | 0 | 53 | 3 |
| Total number of research agreements signed by research firm in previous 3 years with exact technology match | 580 | 1.95 | 2.92 | 0 | 18 | 1 |
| Any unilateral termination rights? | 580 | 0.97 | | 0 | 1 | 1 |
| Any termination rights for financing firm? | 580 | 0.96 | | 0 | 1 | 1 |
| Any unconditional termination rights for financing firm? | 580 | 0.39 | | 0 | 1 | 0 |
| Any unconditional termination rights for financing firm and broad intellectual property rights? | 580 | 0.11 | | 0 | 1 | 0 |
| Carter-Manaster rank of lead bank in research firm's IPO | 526 | 7.71 | 1.99 | 1 | 9 | 8.75 |

of the analysis, we determine if the two parties had a previous research collaboration covering the same set of technologies), contracts involving three or more independent parties (determined from the text of the agreements), and agreements where the financing firms held at least a 50 percent stake in, or a purchase option for, the research firm at the time the agreement was negotiated (determined through a review of securities agreements). We also eliminate three agreements that appear twice in the ReCap database and one agreement that was subsequently dropped from the database. The resulting sample consists of 580 contracts. We carefully examine the contracts and code the key features relevant to our analysis (see discussion below).

Table 2 summarizes the contractual features. The dates of the research agreements range from 1980 to 2001, with a disproportionate representation of later contracts due to the growth of activity in the industry. The research collaborations range widely in length, averaging about four years (in the smaller subset of contracts for which the information about duration is provided).

The focus of our analysis is to relate the differences in contract design to differences in the contractibility of the research activities. To measure variations in contractibility, we rely on ReCap's

description of how concretely the main research target is specified. Our primary distinction is between agreements that build upon a well-defined lead product candidate and those where the research program is described in more general terms, without referring to a specifiable lead product candidate. Our rationale is that, in the latter settings, it is hard to specify the exact research tasks and, hence, the contractual partners cannot directly use contingent contracting to deal with the problem of cross-subsidization.

While we rely on ReCap's classification of more or less contractible research, the distinction is also rather apparent from the language in the contracts. Research agreements that lack a specific compound or process are vaguer and involve a broader "discovery" phase. Web Appendix C provides excerpts from the "Field of Use" section or the preamble of four contracts, which define the scope of the collaboration (as specified by ReCap). Two excerpts are from contracts with specified lead product (ISIS and Eli Lilly 2001; Celgene and Novartis 2000), and two are from contracts without specified lead product (Cubist and Novartis 1999; Millennium BioTherapeutics and Eli Lilly 1997). These excerpts illustrate that the level of detail and specificity is much lower in contracts without a specified lead product candidate. As a result, it is harder to pin down the concrete research tasks.

As shown in Table 2, the lead product is not specified in 37 percent of our observations and is ambiguous in another 11 percent. We have also constructed alternative, more narrowly defined measures of contractibility, which we will discuss below (Section IVB). The results are little changed.

Table 2 also shows some summary data on other characteristics of the research agreements. We identify contracts with diagnostic and veterinary products (13 percent and 5 percent) since the scientific and regulatory uncertainties are considered to be lower than for therapeutic products. We also separate out biotechnology financing firms (17 percent), which may employ different contracts. Most research firms have only very modest revenues and financial resources, though there are a few positive outliers. One useful summary statistic, denoted as "Financial Health Index," is the ratio of the absolute value of the firm's cash flow (or, if unavailable, net income) to its cash and equivalents. It is the inverse of what venture capitalists often refer to as the "fume date"—the time until the firm will run out of financing if it continues to consume cash at the same rate and does not receive additional financing. If the firm has nonnegative cash flow, the index value is set as zero. We also identify, in the US Patent and Trademark Office database, the number of patents awarded to the research firm by the time the research agreement is signed.

The research firms in the agreements differ substantially in their research capabilities. For instance, there are sharp differences in the seasoning of the key executives and the scientific reputation of the advisors. These quality differences are important to control for since higher-quality firms might be more likely to have specifiable lead products and less likely to be confronted with far-reaching option rights for the financing firm due to stronger bargaining power. In addition, confining the sample to high-quality research firms would be helpful to address uncertainty or asymmetric information about research quality as alternative explanations: *ex ante*, the financing firm cannot perfectly assess the abilities of the researchers and, in case of nonspecifiable lead products, it might therefore reserve the right to end the relationship as soon as it recognizes a low type. Following previous literature, we attempt to parameterize research quality by using the reputation of the investment bank that takes a biotechnology firm public. For example, all else being equal, a biotechnology firm underwritten by Morgan Stanley rather than D. H. Blair is likely to be a higher-quality firm. We use the investment bank ratings compiled by Richard Carter and Steven Manaster (1990), Carter, Frederick H. Dark, and Ajai K. Singh (1998), and Tim Loughran and Jay R. Ritter (2004) from the time when the firm went public. If no rating is available for that period, we employ the rating in the most proximate period. We determine ratings for 526 firms in our sample, ranging from 1 to 9 with a median of 8.75.

IV. Empirical Analysis

The focus of our empirical analysis is the contractual response to variations in the contractibility of research. We begin the analysis by examining the empirical validity of two assumptions that underlie our multitasking model.

A. Evidence on Incentive Conflicts

The ability of researchers to multitask gives rise to conflicts in two ways. First, for a given research project, researchers may emphasize more academic aspects and tests. Second, researchers might work on different projects, either with other collaborators or as stand-alone projects.

We test the first assumption, i.e., whether research firms are more oriented to academic science than the financing firms, by comparing the academic orientation of patented research of both parties. As a measure of the academic nature, we use citations to nonpatented prior art, which in these awards are overwhelmingly to articles in scientific journals. A higher number of citations of scientific journals indicate a more academic orientation.

To implement this analysis, we randomly choose 100 contracts in our sample. For each party, we retrieve the first patent applied for in the month of the contractual agreement.¹² We start with a placebo test, which compares citations to other US patents. These rates should not differ unless the parties differ in citation proclivity more generally. (For instance, smaller companies are more likely to rely on outside counsel to prepare their patent applications, who may be more scrupulous in their citation practices than internal staff.) We find that patents of research firms contain on average 11.8 citations to other patents while the average for financing firms is 10.0. In a paired *t*-test, the means are not significantly different at conventional confidence levels.

We then compare citations to nonpatented prior art, typically academic articles. The average patent of a research firm makes 26.9 such citations, while the mean is 13.7 for financing firms, about half as many. The means are significantly different at the 1 percent confidence level.¹³ Thus, the citation practices indicate that research firms rely more heavily on scientific research.

Second, we examine whether the research firm is juggling multiple projects. We collect data on all research agreements that the firm had entered into with *other* firms in the three years prior to the research agreement in question. (Three years is the median alliance life span.)¹⁴ We find that the research firms in our sample engaged in a mean of 6.4 and a median of four such research agreements in the previous three years. Hence, the typical research firm is indeed involved in more than one collaboration. Moreover, many of these competing collaborations are in closely related fields. ReCap lists up to six classes of technology (such as “Drug Delivery” or “Immunoassay”) for each research agreement. We define a prior agreement as “technologically similar” if one or more of these classes overlap. We find a mean (median) of 4.8 (three) overlapping research agreements.

The evidence on research firms’ scientific orientation and involvement in multiple projects suggests scope for misalignment of incentives between researchers and financing firms.

¹² If a party made no application in that month, we use the first application in the year. If there was no patent application in that year, we use the first application in the prior year or, if there was none in the previous year, in the year after the research agreement.

¹³ The results are slightly more significant with unpaired tests, which allow for slightly larger samples.

¹⁴ See Lerner, Hilary Shane, and Alexander Tsai (2003).

B. *The Use of Termination and Broad Intellectual Property Rights*

We now analyze how the contract design responds to the degree of contractibility. As the outcome variable, predicted by our model, we examine whether the financing firm is granted the unconditional right to unilaterally terminate the agreement and obtains broad rights to the product upon termination.

A wide variety of clauses allows the financing firm to terminate the agreement. However, most of them are conditional on specific events, such as bankruptcy or acquisition of the research firm. We identify three cases where the financing firm can terminate the agreement unconditionally, as predicted by the theory for cases of nonverifiable research effort:

- (i) The financing firm can terminate for any cause, either within a defined time period (e.g., after one year of the agreement's signing) or at any time.
- (ii) The financing firm can terminate the agreement for "misbehavior" or "breach."
- (iii) The financing firm can terminate if it believes that the continuation of the collaboration would be "unwise."

Note that, in theory, the second criterion differs from the others. When a party terminates because of "breach," a court may later find it to be the actual breaching party. With the other two termination provisions, this is almost impossible; no court would second-guess a firm's decision to terminate because continuing was "unwise." In practice, however, termination for "material breach" functions much like an open-ended termination. It allows the terminating party to employ various self-help remedies unless and until the other party goes to court to litigate the issue. In addition, the burden is on the nonterminating party to show the termination was not justified.¹⁵

The bottom rows of Table 2 show that termination rights are a widespread feature. In almost all contracts some kind of termination right is specified (97 percent) and is assigned to the financing firm or both parties (96 percent). More than half of those termination rights are conditional on specific events, while about 39 percent of the research agreements have provisions for the financing firm to terminate the collaboration unconditionally. In 11 percent of the sample, unconditional termination rights are coupled with broad access to the intellectual property in case of termination. The latter contract design conforms exactly to the prediction of the theory: it excludes the research firm from retaining the value generated during the collaboration in case of termination. The model predicts that, while patents and other intellectual property rights are arguably worth more in the hands of the research firm, the threat of reassigning them to the financing firm ensures profit-maximizing research of the biotechnology researchers. Note that the 11 percent frequency likely understates the overall empirical importance of this type of contract design, since our data, which rely on publicly filed documents, disproportionately sample larger research firms. The incentive and contractibility problems highlighted in the paper are less likely to bind in these more liquid firms than in the overwhelming majority of small, nonpublic research firms (Prediction 2).¹⁶

¹⁵ For a discussion of some of these issues in a recent licensing case, see Judge Easterbrook's opinion in *Baldwin Piano Inc. v. Deutsche Wurlitzer GmbH*, 73 USPQ2d 1375 (CA 7 2004).

¹⁶ Even if these terms were used in only 11 percent of research alliances, they would be of significant practical importance. About 700 biotechnology alliances were signed in 2005, with an estimated total value (the sum of promised precommercialization payments) of \$56 billion. For eight of the top ten biotechnology drugs in 2005, a strategic alliance played a key role in the development. Cumulative 2005 sales of these eight drugs were \$23.3 billion (source: <http://www.>

TABLE 3—CONTRACT CHARACTERISTICS

| | Mean number of unconditional termination rights assigned to the financing firm (combined with broad intellectual property rights) | | Test of difference | |
|--|---|-------|---------------------|-----------------|
| | If yes | If no | <i>t</i> -statistic | <i>p</i> -value |
| No specifiable lead product? | 0.21 | 0.11 | 2.66 | 0.008 |
| Research agreement involves diagnostic technologies? | 0.05 | 0.16 | −2.02 | 0.044 |
| Research agreement involves veterinary technologies? | 0.03 | 0.16 | −1.49 | 0.136 |
| Research agreement between two biotechnology firms? | 0.25 | 0.13 | 2.34 | 0.020 |
| Research firm has above median net income? | 0.14 | 0.15 | −0.10 | 0.923 |
| Research firm has high-status underwriter? | 0.20 | 0.13 | 1.55 | 0.114 |

Based on those clauses, we construct the dependent variable in several ways. We use both a binary variable, which indicates if the financing company has at least one unconditional termination right, and an integer variable, which counts the number of termination rights of the financing company from 0 to +3. In both versions, we require that the financing party also obtains broad intellectual property rights upon termination. Alternatively, we consider only cases where the financing firm has the right to terminate (with broad rights) and the research firm has no right to terminate (with or without broadened rights). Again, we construct both the simple binary variable, which takes the value of one if the financing firm has at least one termination right and the research firm has none, and as well as integer variables with values from −3 to +3, counting the “net” termination rights of the financing firm minus those of the research firm. All approaches deliver approximately the same results.

We begin by testing Prediction 1: are agreements about projects without a contractible lead product candidate more likely to grant the financing firm the right to terminate the collaboration and broad access to the intellectual property involved?

We first present a series of simple univariate comparisons (Table 3). Agreements are significantly more likely to assign both termination and broad property rights to the financing firm when there is no specifiable lead product candidate at the time the agreement is signed, as predicted by our model. This type of contract design is also more likely when the agreement does not involve veterinary and diagnostic products (which, as noted in Section III, are likely to have substantially reduced information problems) and when the agreement is between two biotechnology firms, though the differences in frequency are typically insignificant. The differences between firms with high and low net income are also insignificant. Firms that are ultimately underwritten by high-status underwriters are more likely to employ the termination and broad rights clause than those with low-status underwriters, though the *p*-value of the difference is 0.11.

The baseline regression analysis is reported in Table 4. We test whether the number of unconditional termination rights (combined with the assignment of broad intellectual property rights upon termination) is positively related to the lack of specified lead products. We employ a variety of control variables:

- To account for a possible time trend in the transactions, we control for the date of the agreement. We initially employ a continuous date variable and later year fixed effects.

TABLE 4—REGRESSION ANALYSIS OF CONTRACT DESIGN

| | Ordered logit (1) | Ordered logit (2) | OLS (3) | OLS with year fixed effects (4) | OLS with year and firm fixed effects (5) |
|---|-------------------------|-------------------------|---------------------|---------------------------------------|--|
| Date | 0.012 [0.039] | 0.032 [0.043] | 0.005 [0.006] | | |
| No specifiable lead product | 0.678 [0.292]** | 0.680 [0.315]** | 0.126 [0.047]*** | 0.140 [0.049]*** | 0.139 [0.050]*** |
| Unknown if specifiable lead product | −0.110 [0.516] | 0.031 [0.527] | 0.002 [0.070] | −0.011 [0.073] | 0.014 [0.075] |
| Agreement involves diagnostic product | −0.889 [0.540] | −0.794 [0.545] | −0.096 [0.061] | −0.103 [0.064] | −0.097 [0.065] |
| Agreement involves veterinary product | −1.413 [1.034] | −1.336 [1.037] | −0.120 [0.090] | −0.123 [0.095] | −0.107 [0.096] |
| Carter-Manaster rank of lead underwriter of research firm's IPO | 0.003 [0.070] | 0.032 [0.077] | 0.010 [0.011] | 0.009 [0.011] | 0.009 [0.011] |
| Number of patents of research firm | | 0.006 [0.007] | 0.001 [0.001] | 0.001 [0.001] | 0.001 [0.001] |
| Financial Health Index | | 0.732 [0.557] | 0.075 [0.077] | 0.119 [0.083] | 0.119 [0.084] |
| Number of previous research agreements between financing and research firms | | −0.016 [0.352] | −0.005 [0.051] | −0.004 [0.053] | −0.019 [0.054] |
| Constant | | | −10.739 [11.783] | 0.027 [0.490] | −0.12 [0.513] |
| Year fixed effects | | | | X | X |
| Financing firm fixed effects | | | | | X |
| Observations | 526 | 483 | 483 | 483 | 483 |
| R ² | | | 0.04 | 0.07 | 0.09 |

Notes: Dependent variable is the number of unconditional termination rights assigned to financing firm (combined with broad intellectual property rights). Standard errors in brackets.

***Significant at the 1 percent level.

**Significant at the 5 percent level.

*Significant at the 10 percent level.

- We include dummies for diagnostic and veterinary products, and the underwriter rank.
- We also identify, in the US Patent and Trademark Office database, the number of patents awarded to the research firm by the time the research agreement is signed. As discussed below, the cross-subsidization problems may be more severe in research firms that hold many patents.
- To control for capital constraints, we use the Financial Health Index defined above.
- We include the number of previous research agreements between the same parties. Prior interactions may allow firms to accumulate reputational capital and ease the contracting.

Table 4 presents a number of regressions, which use some or all of these independent variables, trading off completeness and sample size or selection. (The lower half of Table 1 documents how the use of different control variables affects the sample size.) We employ both ordered logit and ordinary least squares (OLS) specifications. The ordered logit is more suitable given the ordinal, nonnegative nature of the dependent variable, though the estimation fails to achieve convergence in smaller subsamples or after including a large number of controls. Finally, we employ fixed effects for the thirteen most frequently represented financing firms in addition to the year fixed

effects. The firm dummies are created for the entities that entered into the agreement, even if the firm was subsequently merged or acquired (e.g., American Home Products or Sandoz).¹⁷

Columns 1 and 2 present the ordered logistic estimations, with the reduced and the full set of control variables, respectively. In both specifications, we estimate a coefficient of 0.68, significant at the 5 percent confidence level. Hence, if an agreement does not specify the lead product, the odds of having termination rights with broad property right reversion over the odds of having none increases by 97 percent compared to an agreement with specified lead product, consistent with the raw statistics in Table 3. The estimated odds ratio is larger than the raw odds ratio without controls: the frequency of contracts with at least one unconditional termination right with broad property rights is 15 percent among contracts without a specifiable lead product and 9 percent otherwise, resulting in an odds ratio of 1.72. All other coefficient estimates are highly insignificant.

We observe a consistent pattern in the OLS estimations (and many dozens of similar unreported analyses). The estimated effect of not having a specifiable lead product is 0.13 when including the full set of controls and 0.14 when using all controls and year fixed effects instead of the continuous date variable. This result is not only statistically, but also economically significant relative to the mean of the dependent variable (0.15).¹⁸ Thus, regardless of the estimation method and specification, we find that research collaborations in which the research task is hard to contract on (due to the lack of a specifiable lead product) are associated with a significant increase in the assignment of termination rights and of broadened intellectual property rights to the financing firm.

As in the logistic analysis, all other explanatory variables have little predictive power. While none of our hypotheses predicts that these control variables should have higher predictive power, one may still find it surprising that we fail to estimate any significant effects across all specifications (with the exception of year and financing company fixed effects). However, the poor power of the controls might simply reflect the imprecision of these measures. In fact, the lack of explanatory control variables with high statistical power is rather common in the empirical analysis of real-world and nonstandardized contracts.¹⁹

A natural concern in this analysis is endogeneity. For instance, a major issue that affects the entire empirical literature on alliances is the endogenous choice to sign a contract. Financing firms entering into research alliances are likely to be different from those not entering. These differences may affect the observed contract design. While there is no obvious reason why the endogenous entry decision would affect the relationship between specified lead products and option clauses, we will address the selection issue directly below. In particular, we will check that our results are not driven by endogenous matching between low-ability research types and financing firms that (opportunistically) insist on termination rights.

A first step toward addressing these concerns is the inclusion of firm dummies in the estimation reported in column 5 of Table 4. The inclusion of dummies for the 13 most frequently represented financing firms, while jointly significant, has little impact on the other coefficients. Both the statistical and the economic magnitude of the coefficient of interest, the estimated effect of “no specifiable lead product,” are unaffected compared to the regression including only year fixed effects. These results support the interpretation that, for a given financing firm, the variation in termination and broad intellectual property rights is indeed related to the research program. The results also alleviate the larger endogeneity concerns pointed out before: the occurrence of different types of

¹⁷ In addition, we reran the fixed-effects regression using the entity as it existed in 2003. Thus, we coded the Novartis dummy variable as one whether the agreement was signed by Ciba-Geigy, Novartis, or Sandoz. The results were essentially unchanged.

¹⁸ The R^2 is similar to other empirical work analyzing nonstandardized contracts, such as Robinson and Stuart (2007).

¹⁹ For example, in Abhijit Banerjee and Esther Dufo (2000), none of “contract” and “project characteristics” and only one of the “firm and client characteristics” are significant in the eight regressions analyzing contract design.

contracts within the same financing firm ensures that our results are not driven by the fact that certain types of companies enter research agreements only with specified lead-product candidates, while other types of companies enter only those without.²⁰

We will further address the concern about endogeneity and omitted variables below, when testing Prediction 2 and comparing the results on various subsamples. Before turning to the second set of results, however, we evaluate more closely our proxy for “noncontractibility of research,” the lack of a specifiable lead product candidate. The proxy is constructed to capture contracting situations in which it is hard to describe and verify the tasks to be performed by the research firm. We test our interpretation of this proxy and of the baseline result by measuring the research firm’s incentives to work on different tasks more directly. One measure of the incentives for “project substitution” is the number of parallel projects that the research firm is involved in and that concern the same technology. We construct such a proxy using data on all other research agreements that the company had entered into or filed in the three years prior to the contract in our sample.²¹ The summary statistics of the alternative proxy are in the lower half of Table 1 (and are discussed above).

In the first two columns of Table 5, we test whether the alternative measure predicts the use of contracts with termination option and product reversion. We include the full set of controls as well as year and firm fixed effects. In column 1, we find that the proxy is associated with a significant increase in the use of such option contracts. As before, all other controls are insignificant. Thus, we replicate our main result using the alternative measure. In column 2, we include this proxy along with our baseline measure of “no specifiable lead product.” Here, our baseline measure remains economically and statistically significant, while the new proxy becomes insignificant. We obtain similar results (i) when restricting the count to research agreements in similar technologies (defined as being classified by ReCap into the same technology classes), (ii) when also using research agreements signed in the three years after the sample contract was signed (on the grounds that they also introduce contracting challenges, and might have been at least partially anticipated), and (iii) when using cross-tabulations rather than regressions. Hence, our empirical proxy appears to capture the multitasking problem laid out in the theoretical analysis.

A second set of tests addresses the concern that the measure of “no lead product” may identify other variations in the contracting situation. For example, in agreements without a specifiable lead product, the financing firm might contribute more than money, such as knowledge or methods, as noted in the ALZA case (see Web Appendix A).

To address the concern about unobserved heterogeneity, we restrict the sample of contracts in several ways. First, we exclude financing firms that appear to have technological know-how in the area of the contracted research. We identify the area of contracted research from the short contract description prepared by ReCap. This description is typically based on the introductory paragraphs of an agreement, which define its scope. We tabulate all words in the text strings of the descriptors by frequency and retain those words and abbreviations that describe either a disease or technology.²² We then use US Patent and Trademark Office data²³ to search for patent applications by the financing firm that contain either all of or any of the same keywords in the patent abstract and that the financing firm had already applied for at the time of the research agreement. One subtle issue

²⁰ In unreported analyses, we repeat the regressions, clustering the standard errors in the analyses by research firm. This modification has little impact on the results.

²¹ We also attempted to measure incentives for project substitution by examining the total number of projects, as well as the progress of their drugs through clinical trials. Unfortunately, neither of the two main data sources, the “Clinical Trials” section of the ReCap database and PharmaProjects, permits such an analysis, mostly due to missing dates.

²² As a robustness check of this mechanical strategy, we assigned the task of identifying disease and technology keywords in the descriptions to two biology students. The resulting lists of keywords were remarkably similar.

²³ The USPTO patent database can be accessed at <http://appft1.uspto.gov/netahtml/PTO/search-adv.html> and records all patents from 1976 onward.

TABLE 5—REGRESSION ANALYSIS OF CONTRACT DESIGN: ALTERNATIVE PROXIES AND ADDITIONAL CONTROLS

| | Alternative proxy for incentive conflicts (multitasking): other research agreements | | Sample excludes financing firms with related patents | | Sample restricted to agreements not defined as joint ventures by ReCap | Sample excludes agreements where text indicates that financing firm is also involved in research | Sample excludes agreements on veterinary and diagnos- tic products | With fixed effects for disease categories |

**Significant at the 5 percent level.

*Significant at the 10 percent level.

is whether one counts only patent applications of the firm itself or also those of firms with which it had merged by the time of the research agreement. In the reported results, we include the research of the merged entities. (To identify the patent applications of those firms, we retrieved the history of all mergers and acquisitions for the period 1975–2001 using the SDC Mergers and Acquisitions database. All results are robust to examining just the activity of the firm itself.) In each case, we employ only patent applications that were ultimately issued because, for the bulk of the sample period, the US Patent and Trademark Office did not disclose unsuccessful patent applications.

Table 5 shows the results of the baseline analysis after eliminating contracts where the financing firm had already filed patent applications with *any* of the same keywords (column 3) or after eliminating the smaller number where a filing had *all* of the keywords (column 4). In each case, the results are similar to our baseline specifications. We undertook a large number of robustness

checks, such as cross-tabulations and using different searches (for instance, altering the keywords employed, the sections of the patents to search, and the patents examined), and consistently found that the cases where the financing firms had significant technological capabilities were little different from the others in this regard.

We also examined the responsibilities delineated in the contracts themselves and excluding those where the contractual language suggests a higher involvement. We employ two approaches. In column 5, we report the results of an analysis where we eliminated agreements classified by ReCap as “joint ventures,” “joint R&D,” and “collaborations.” In column 6, we report the results of an analysis based on our own reading of the contracts. We classify the agreements into those where the role of the financing firm is unambiguously providing only financing (214 cases), those where there is a role in the research process (150), and those where a determination could not be made with certainty (216). In the reported regression, we eliminate observations where the financing firm unambiguously played a role in the research process. With both approaches, we find that a strong relationship remains between a non-contractible lead product and the assignment of unilateral termination and broad intellectual property rights to the financing firm.

The final two columns of Table 5 address the heterogeneity concern by eliminating agreements about diagnostic and veterinary products, which may be different, e.g., due to the expedited review process (column 7), and by adding controls for the various diseases that are the subject of the agreement (column 8). In the reported regression, we employ the disease classifications undertaken by ReCap, but the results are robust to using our own, more detailed scheme, which we constructed with the help of two medical doctors. In both cases, the results are robust.

C. The Role of Financial Constraints

We now test Prediction 2 and examine the impact of financial constraints on the contract design. As discussed in Section IIB, our prediction about contract design depends on the assumption of an illiquid research firm. If the research firm is liquid, the parties can design the contract with termination option such that the financing firm obtains the same payoff as in the first best under full contractibility, namely, by agreeing on a payment from the *research* firm to the financing firm upon termination. Hence, option contracts are not more costly than unconditional contracts and may be observed both when research is contractible and when it is not. As a result, we do not have a theoretical prediction for the subset of liquid research firms.

Prediction 2 suggests performing our core test only in the subsample of financially constrained firms. We started with the overall sample since we do not have a perfect measure of constraints and since research firms are generally considered to be illiquid. Our sample of research firms, however, includes many companies that have gone public. Large and established firms may be significantly less constrained than biotechnology start-ups. In the second step of our analysis, we reestimate on the most constrained subset of firms.

We identify research firms that are constrained by examining their net income in the year prior to the research collaboration. We separate research firms with a net income above and below that of the median firm (in 2002 dollars).

In the regressions reported in columns 1 and 2 of Table 6, below-median firms display a statistically significant relationship between the provisions of termination and broad intellectual property rights and contractibility. For above-median firms, the coefficient is roughly half the size and insignificant. The differences between the coefficients are not statistically significant at conventional confidence levels. As noted above, however, only the coefficient in the low net-income sample is relevant since the theory predicts a significant relationship only among

TABLE 6—SEPARATING RESEARCH FIRMS WITH HIGH AND LOW NET INCOME

financially constrained firms. We do not have a prediction for the high net-income sample. The lack of significance among high-income firms neither confirms nor contradicts our theory.²⁴

We find the same basic pattern after adding year and financing-firm fixed effects (columns 3 and 4). We also find the same pattern when we estimate a pooled regression that includes all observations and separate dummy variables for research firms above and below the median net income, as well as their interactions with indicators for “no” and “unknown specifiable lead product.” In unreported regressions, we also explore the robustness of these results to other definitions of capital constraints. When we isolate the more extremely constrained subset of firms in the bottom quartile of net income, the results become even sharper. Also, when we divide firms on the basis of cash and equivalents on their balance sheets into above and below median, the results are qualitatively similar, though the divisions are weaker. This may reflect the fact that cash is a worse proxy for the financial constraints of biotechnology firms, since they do not raise their financing all at once, but in a series of offerings. Thus, a firm with a strong investor clientele may have access to the capital markets even though its cash in hand is relatively modest.

²⁴ Variations of our model would predict significant differences, e.g., frictions or transaction costs arising from option contracts.

D. Alternative Explanations

We consider three alternative interpretations of the observed contract design.

Research Abilities.—The “unspecified lead product” variable may capture uncertainty or asymmetric information about the “type” of the researchers: ex ante, the financing firm cannot perfectly assess the abilities of the researchers and the chances of a successful collaboration. Termination rights allow the financing firm to end the relationship as soon as it recognizes a low type.

In order to address this concern, we return to the underwriter control introduced in Section III. Higher-quality underwriters indicate higher-quality research firms. Research firms also benefit from the “certification” implicit in high underwriter quality, reducing the uncertainty about their type. Following previous literature, we use a Carter-Manaster (1990) style score to proxy for underwriter reputation. If the difficulty of discerning the research firm’s type explained the use of the option contract, the relationship between option contracts and (non-)contractibility should be stronger among the lower-reputation (below median) firms than among high-reputation firms.

In columns 1 and 2 of Table 7, we find that the effects are instead economically larger and statistically significant only in the subset of research firms with the highly-ranked underwriters. The result is robust to the inclusion of year and firm fixed effects (columns 3 and 4), though the significance diminishes. The same picture emerges in a pooled regression, including interactions of the high-rank and low-rank dummies with our lead-product proxy. The differences between the subgroups are, however, insignificant. We conclude that there is no evidence of stronger effects for lower-quality firms.²⁵

The adverse selection hypothesis also fails to explain why the financing firm obtains broader product rights upon termination. The reversion of broad intellectual property from low research types is likely to be of little value to the financing firm. Hence, for this alternative explanation to hold, our results would need to be driven by the termination right, not by the broad intellectual property rights. However, if we repeat the analysis above using the “termination rights only” (again coded as 0 to +3) as the dependent variable, without requiring the reversal of broad intellectual property rights, contractibility has no significant effect (see the first four columns of Table 8).

Variations in Uncertainty, Informational Asymmetry, or Incentive Misalignment.—The hypothesis put forward in this paper attributes variations in contract design to the lack of contractibility, holding uncertainty, informational asymmetry, and incentive conflicts constant. Alternatively, variations in the latter variables may determine contract design. For instance, termination and broad intellectual property rights may be a response to higher uncertainty about the outcome or higher informational asymmetry between the financing and the research firm.

Additional empirical results cast doubt on these interpretations. A first indication is our prior finding that controls for the type of research program (therapeutic, diagnostic, and veterinary) do not affect the results, even though, as noted above, the scientific and regulatory uncertainty is substantially higher for therapeutic products. Even if we eliminate undesired heterogeneity and examine only agreements about therapeutic products (Table 5, columns 7 and 8), our baseline results hold, with a coefficient of 0.16–0.17 (and a standard error of 0.05–0.06).

Second, we have already shown that “termination rights only” are not related to contractibility (first four columns of Table 8), casting doubt on the interpretation that termination rights are a response to mere informational asymmetries.

²⁵ While these results allow us to reject the alternative hypothesis, they raise the question as to why this relationship should be stronger among the high-quality firms. One possibility is that the observations of firms with lower-quality underwriters are much noisier. Endogenous selection may lead to only “safe” (contractible) cases being contracted.

TABLE 7—SEPARATING RESEARCH FIRMS WITH HIGH AND LOW REPUTATION UNDERWRITERS

| | High-rank underwriter (1) | Low-rank underwriter (2) | High-rank underwriter (3) | Low-rank underwriter (4) |

| R ² | 0.07 | 0.02 | 0.17 | 0.12 |

Notes: Dependent variable is the number of unconditional termination rights assigned to financing firm (combined with broad intellectual property rights). Standard errors in brackets.

***Significant at the 1 percent level.

**Significant at the 5 percent level.

*Significant at the 10 percent level.

Third, heterogeneity in information or incentives would also predict variation in *specified* termination provisions, which are triggered by distinct events such as a change in control, a bankruptcy, or the termination of another agreement. We test for such a relationship using as the dependent variable the interaction between the number of termination provisions (here between 0 and 4) and an indicator of broad intellectual property rights reverting to the financing firm. The results, shown in columns 5 and 6 of Table 8, are quite different from our baseline finding. *Specified* termination rights and broad intellectual property rights are not more frequently assigned in transactions without a specified lead product. This result is consistent with our theory: unconditional termination rights substitute for conditional contracting.

Bargaining Power.—Another explanation for the contracting pattern is the relative bargaining power of the two parties: research firms without well-developed products may be subjected to stronger control rights. We cannot observe bargaining power directly and thus cannot reject this possibility with certainty. Some of the evidence above, however, is hard to reconcile with this interpretation. First, we found that our core results (Tables 4 and 5) are robust to including an increasing number of control variables. In particular, the number of patents of the research firm, its financial strength, the number of other research agreements, and the financing environment for biotechnol-

Notes: Dependent variable in regressions (1) through (4) is the total number of unconditional termination rights assigned to financing firm. Dependent variable in regressions (5) and (6) is the number of conditional termination rights assigned to financing firm (combined with broad intellectual property rights). Standard errors in brackets.

***Significant at the 1 percent level.

**Significant at the 5 percent level.

*Significant at the 10 percent level.

ogy firms more generally should at least partially capture variations in the bargaining power, and thereby reduce the partial correlation between the “no specifiable lead product” variable and the unobserved bargaining power. Instead, as we add independent variables, the magnitude and significance of the “no specifiable lead product” variable increases. Note, however, that the generally low explanatory power of the control variables limits the viability of this argument.

Second, underwriter reputation also serves as a plausible proxy for bargaining power. We found the strongest effect on contract design for research firms with higher-reputation underwriters and thus, supposedly, more bargaining power, contradicting the bargaining interpretation.

V. Conclusion

The design of biotechnology research agreements provides insights into the contractual response to limited contractibility. If the precise task to be performed by one of the parties cannot be specified in the contract, firms respond by assigning unilateral decision rights. Differently from the emphasis on asset ownership rights in previous literature, the parties utilize endogenous decision rights (namely, termination clauses) to solve the problem of contractual incompleteness.

Part of the contribution of this paper is that it sheds light on the nature of the incentive and contracting problem in research alliances, in particular the problem of project substitution or project cross-subsidization. Moreover, we provide new details on the contractual design in research agreements, which are consistent with the theory proposed in this paper, but which also may help to better understand interfirm organizations more generally.

The right to terminate is only one of a complex array of decision rights inherent in research collaborations. There may well be other empirical approaches to testing the theoretical hypotheses in this paper, for instance, examining the shifting terms of agreements that are renegotiated. The analysis underscores the promise of combining theoretical and empirical approaches to understand contract design.

APPENDIX A: MODEL NOTATION

| | |
|-----------------|--|
| R | Research firm |
| F | Financing firm |
| t | Time period (0, 1, 2, and 3) |
| I | Initial investment, required to generate any research surplus |
| e_N | “Narrow” research effort by R |
| e_B | “Broad” research effort by R |
| N | Narrow surplus, i.e., profits from product targeted in the collaboration |
| \bar{N} | High value of narrow surplus |
| \underline{N} | Low value of narrow surplus |
| B | Broad surplus, i.e., profits from other products and collaborations with other firms |
| \bar{B} | High value of broad surplus |
| \underline{B} | Low value of broad surplus |
| ε | Share of B that F captures if it has the rights to the broad surplus |
| α | Share of N that F captures after termination if F has the rights to the narrow surplus |
| p | Payment from F to R |
| p_T | Payment from F to R conditional on termination |
| p_C | Payment from F to R conditional on continuation |
| Δ | $(1 - \alpha)\underline{N} - \varepsilon\bar{B}$ |
| Γ | $(1 - \alpha)\bar{N} - \varepsilon\underline{B}$ |
| o | Property rights assigned to F ; equal to \emptyset (no rights), N , B , or $N + B$ |
| o_T | Property rights assigned to F in case of termination |
| o_C | Property rights assigned to F in case of continuation |
| A | Contract or set of contracts between F and R |
| A_{NO}^* | Set of no-option contracts that maximizes F 's profit when e is not contractible |
| A_O | Options contracts (i, p_C, p_T, o_C, o_T) defined by the party i who has the right to terminate, by the prices p_C and p_T , and by the ownership rights o_C and o_T |
| \hat{A}_O | Option contracts $(F, p_C, p_T, N, N + B)$ that satisfy (2) in Lemma 2 |

| | |
|---------------|--|
| Π | Profit of F |
| Π_{NO}^* | Profit of F from a no-option contract A_{NO}^* , equal to $\max\{\underline{N} - I, 0\}$ |
| Π_O | Profit of F from an option contract A_O |
| $\hat{\Pi}_O$ | Profit of F from an option contract \hat{A}_O |

APPENDIX B

PROOF OF LEMMA 1:

To induce e_N given the allocation $o_C = N$ and $o_T = N + B$, F needs to terminate after e_B and to continue after e_N ; under any other termination rule, R would choose e_B because of assumption (A2) and $\bar{B} > B$.

Under the contractual provisions $i = F$, $o_C = N$, and $o_T = N + B$, F terminates after e_B if and only if $\underline{N} - p_C \leq \alpha \underline{N} + \varepsilon \bar{B} - p_T$ and continues after e_N if and only if $\bar{N} - p_C > \alpha \bar{N} + \varepsilon \underline{B} - p_T$. Solving these two inequalities for $p_C - p_T$ yields (1). Given F 's conditional termination decisions, R receives payoff p_T after e_B and $\underline{B} + p_C$ after e_N . Hence, R chooses e_N if and only if $p_C - p_T > -\underline{B}$, which holds given (1) and (A1). Hence, prices (p_C, p_T) satisfying (1) are necessary and sufficient to induce F to terminate if and only if R chooses e_B .

PROOF OF LEMMA 2:

The maximization program of F within the set of option contracts satisfying (1) is

$$\begin{aligned}
 & \max_{p_C, p_T} \bar{N} - p_C - I, \\
 & \text{s.t. } \Gamma > p_C - p_T \geq \Delta, \\
 & p_C + \underline{B} \geq \underline{B}, \\
 & p_C \geq 0, p_T \geq 0,
 \end{aligned}$$

where the first constraint is simply double-inequality (1) from Lemma 1, which ensures incentive compatibility for R and F ; the second is the participation constraint for R given reservation utility \underline{B} from assumption (A3), and the constraints in the last line capture R 's financial constraints. We can simplify this program to

$$\begin{aligned}
 & \min_{p_C, p_T} p_C \\
 & \text{s.t. } p_C < \Gamma + p_T, \\
 & p_C \geq \Delta + p_T, \\
 & p_C \geq 0, p_T \geq 0.
 \end{aligned}$$

We distinguish three subcases: (i) If $\Gamma > \Delta \geq 0$, then $p_C \geq 0$ is redundant and setting $p_C = \Delta$ and $p_T = 0$ is optimal. (ii) If $\Gamma > 0 > \Delta$, then the nonnegativity constraint on p_C is binding if $p_T < -\Delta$. Therefore, setting $p_C = 0$ and picking any $p_T \in [0, -\Delta]$ is optimal. (iii) Similarly, if $0 \geq \Gamma > \Delta$, the nonnegativity constraint on p_C is binding for $p_T < -\Delta$, and setting $p_C = 0$ requires $-\Gamma < p_T \leq -\Delta$.

PROOF OF LEMMA 3:

If $\underline{N} - I \geq 0$, then $\hat{\Pi}_O > \Pi_{NO}^* \Leftrightarrow \bar{N} - \underline{N} > \max\{\Delta, 0\} \Leftrightarrow \bar{N} - \underline{N} > \Delta$, where the last biconditional follows from $\bar{N} > \underline{N}$. If $\underline{N} - I < 0$, then $\hat{\Pi}_O > \Pi_{NO}^* \Leftrightarrow \bar{N} - I > \max\{0, \Delta\} \Leftrightarrow \bar{N} - I > \Delta$, where the last biconditional follows from the assumption $\bar{N} > I$. The two cases can be summarized as $\hat{\Pi}_O > \Pi_{NO}^* \Leftrightarrow \bar{N} - \max\{\underline{N}, I\} > \Delta$.

PROOF OF PROPOSITION 1:

We consider separately option contracts with $i = F$ and with $i = R$.

1. Among option contracts with $i = F$, we distinguish (i) contracts inducing termination in equilibrium, (ii) those inducing continuation in equilibrium but with $o_C \neq N$, and (iii) those inducing continuation in equilibrium and with $o_C = N$ but with $o_T \neq N + B$. We compare, in turn, the payoffs F reaps under each of these sets of contracts with F 's payoff under the best possible no-option contract A_{NO}^* and under a contract \hat{A}_O , and show that these payoffs—if they exceed the best possible no-option payoff Π_{NO}^* at all—are strictly smaller than the payoff under \hat{A}_O , $\hat{\Pi}_O$.

(i) For option contracts inducing termination in equilibrium, we distinguish four cases:

If $o_T = \emptyset$, then $\Pi_O = -p_T - I < 0 \leq \Pi_{NO}^*$ (given $p_T \geq 0$).

If $o_T = B$, then $\Pi_O = \varepsilon B - p_T - I$, where R 's participation constraint implies $p_T \geq \underline{B}$ and thus, with (A1) $\Pi_O < 0 \leq \Pi_{NO}^*$.

If $o_T = N$, then $\Pi_O = \alpha N - p_T - I \leq \alpha N - I < \hat{\Pi}_O$.

If $o_T = N + B$, then $\Pi_O = \alpha N + \varepsilon B - p_T - I$, where R 's participation constraint implies $p_T \geq \underline{B}$ and thus, with (A1) $\Pi_O < \alpha N - I < \hat{\Pi}_O$.

(ii) Among option contracts inducing continuation in equilibrium but not allocating (only) the narrow rights to F , $o_C \neq N$, we distinguish three cases:

If $o_C = \emptyset$, then $\Pi_O = -p_C - I \leq 0 \leq \Pi_{NO}^*$.

If $o_C = B$, then $\Pi_O = \varepsilon B - p_C - I$, where R 's participation constraint implies $p_C \geq \underline{B}$ and thus $\Pi_O < 0 \leq \Pi_{NO}^*$.

If $o_C = N + B$, then $\Pi_O = N + \varepsilon B - p_C - I$, where R 's participation constraint implies $p_C \geq \underline{B}$; (A2) implies that F needs to terminate after e_B (or R would choose e_B and the resulting payoff for F is strictly smaller than Π_{NO}^*); the incentive-compatibility constraints such that F continues if and only if $e = e_N$ are

$$\left. \begin{array}{l} \bar{N} + \varepsilon \underline{B} \\ \bar{N} \\ (1 - \alpha) \bar{N} + \varepsilon \underline{B} \\ (1 - \alpha) \bar{N} \end{array} \right\} > p_C - p_T \geq \left\{ \begin{array}{ll} \underline{N} + \varepsilon \bar{B} & \text{if } o_T = \emptyset \\ \underline{N} & \text{if } o_T = B \\ (1 - \alpha) \underline{N} + \varepsilon \bar{B} & \text{if } o_T = N \\ (1 - \alpha) \underline{N} & \text{if } o_T = B + N \end{array} \right.$$

and the incentive-compatibility constraint ensuring that R chooses e_N is

$$p_C - p_T > \begin{cases} \bar{B} & \text{if } o_T = \emptyset \\ 0 & \text{if } o_T = B \\ \underline{B} & \text{if } o_T = N \\ 0 & \text{if } o_T = B + N. \end{cases}$$

An equilibrium exists, i.e., all four conditions (participation constraint, the two inequalities of F 's incentive constraint, R 's incentive constraint) are satisfied if

$$\begin{aligned} \bar{B} < \bar{N} + \varepsilon \underline{B} \quad \text{and} \quad \bar{N} - \underline{N} > \varepsilon(\bar{B} - \underline{B}) & \quad \text{for } o_T = \emptyset \\ \underline{B} < \bar{N} & \quad \text{for } o_T = B \\ \bar{B} < (1 - \alpha)\bar{N} + \varepsilon \underline{B} \quad \text{and} \quad (1 - \alpha)(\bar{N} - \underline{N}) > \varepsilon(\bar{B} - \underline{B}) & \quad \text{for } o_T = N \\ \underline{B} < (1 - \alpha)\bar{N} & \quad \text{for } o_T = B + N. \end{aligned}$$

In these cases, the maximization problem of F amounts to minimizing p_C under the constraints above, and we can bound the optimal p_C^* (if it exists):

$$p_C^* \geq \begin{cases} \max\{\bar{B}, \underline{N} + \varepsilon \underline{B}\} & \text{for } o_T = \emptyset \\ \max\{\underline{B}, \underline{N}\} & \text{for } o_T = B \\ \max\{\bar{B}, (1 - \alpha)\underline{N} + \varepsilon \bar{B}\} & \text{for } o_T = N \\ \max\{\underline{B}, (1 - \alpha)\underline{N}\} & \text{for } o_T = B + N. \end{cases}$$

It is easy to check that the payoff $\Pi_O = \bar{N} + \varepsilon \underline{B} - p_C^* - I$ is smaller than $\hat{\Pi}_O$ in all four cases, even if we set p_C^* equal to its lower bound.

- (iii) For contracts inducing continuation with $o_C = N$ but $o_T \neq N + B$, note first that $o_C = N$ implies that the participation constraint for R is not binding since R receives \bar{B} . Also, as above, (A2) implies that F needs to terminate after e_B (otherwise, R would choose e_B and the resulting payoff for F would be strictly smaller than Π_{NO}^*). The incentive compatibility constraints ensuring that F continues if and only if e_N is

$$\left. \begin{aligned} & \bar{N} \\ & \bar{N} - \varepsilon \underline{B} \\ & (1 - \alpha)\bar{N} \end{aligned} \right\} > p_C - p_T \geq \begin{cases} \underline{N} & \text{for } o_T = \emptyset \\ \underline{N} - \varepsilon \bar{B} & \text{for } o_T = B \\ (1 - \alpha)\bar{N} & \text{for } o_T = N, \end{cases}$$

and the incentive compatibility constraint ensuring that R chooses e_N is

$$p_C - p_T > \begin{cases} \bar{B} - \underline{B} & \text{if } o_T = \emptyset \\ -\underline{B} & \text{if } o_T = B \\ \bar{B} - \underline{B} & \text{if } o_T = N. \end{cases}$$

The constraints imply additional conditions for existence in two cases:

$$\bar{B} - \underline{B} < \begin{cases} \bar{N} & \text{if } o_T = \emptyset \\ (1 - \alpha) \bar{N} & \text{if } o_T = N. \end{cases}$$

The maximization problem amounts to minimizing p_C under the above constraints and yields:

$$p_C^* = \begin{cases} \max \{ \bar{B} - \underline{B}, \bar{N} \} & \text{for } o_T = \emptyset \\ \max \{ \underline{N} - \varepsilon \bar{B}; 0 \} & \text{for } o_T = B \\ \max \{ \bar{B} - \underline{B}, (1 - \alpha) \underline{N} \} & \text{for } o_T = N \end{cases}$$

and the resulting payoff $\Pi_O = \bar{N} - p_C^* - I$ is strictly smaller than $\hat{\Pi}_O$ in all three cases.

Summarizing cases (i) to (iii), we have shown that there is no alternative option contract with $i = F$ such that its payoff $\Pi_O > \Pi_{NO}^*$ and $\Pi_O \geq \hat{\Pi}_O$.

2. For the class of contracts with $i = R$, contracts that neither (i) induce continuation in equilibrium nor (ii) allocate narrow rights to F after continuation are ruled out the same way as for $i = F$. Contracts satisfying (i) and (ii) allocate at least narrow rights after continuation and will thus always induce R to choose e_B , since R 's payoff after continuation if choosing e_N is always weakly (for $o_C = N + B$) or strictly (for $o_C = N$) smaller than if choosing e_B . However, the maximum payoff resulting from any contract inducing R to choose e_B is Π_{NO}^* . Thus, there is also no option contract with $i = R$ and payoff Π_O satisfying $\Pi_O > \Pi_{NO}^*$ and $\Pi_O \geq \hat{\Pi}_O$.

LEMMA 1'': *An option contract (i, p_C, p_T, o_C, o_T) with $i = F$, $o_C = N$, and $o_T = \emptyset$ implements e_N if and only if*

$$(1'') \quad \bar{N} > p_C - p_T \geq \underline{N} \quad \text{and} \quad p_C - p_T > \bar{B} - \underline{B}.$$

PROOF:

Notice that the set of admitted values for $p_C - p_T$ described in (1'') is nonempty since we are considering the case $\bar{N} + \underline{B} > \underline{N} + \bar{B}$.

The condition $p_C - p_T \geq \underline{N}$ guarantees that F chooses to terminate when $e = e_B$. The condition $\bar{N} > p_C - p_T$ guarantees that F chooses to continue when $e = e_N$. Finally, $p_C - p_T > \bar{B} - \underline{B}$ guarantees that R chooses e_N .

Moreover such a contract can be implemented with the following prices:

LEMMA 2'': *In the set of option contracts $(F, p_C, p_T, N, \emptyset)$ that implement e_N , setting $p_C = 0$ and $-\bar{N} < p_T \leq -\underline{N}$ and $p_T < -(\bar{B} - \underline{B})$ maximizes F 's payoff.*

PROOF:

The prices implement e_N by Lemma 1. Since the equilibrium payoff of R under this contract is its reservation utility \underline{B} , the profit of F cannot be increased further without violating the participation constraint of R .

Lemma 2 illustrates that there are several types of option contracts achieving the same maximum payoff for F as option contracts in \hat{A}_O .
